# XML Xpath Terminology

- XPath is a language for finding information in an XML document. XPath is used to navigate through elements and attributes in an XML document. The primary purpose of XPath is to address parts of an XML document.
- Shred or extract parts of an XML Document
- The XML representation of schema components uses a vocabulary identified by the namespace name `http://www.w3.org/2001/XMLSchema`. For brevity, the text and examples in this specification use the prefix `xs:` to stand for this namespace; in practice, any prefix can be used.

`//author` - All `<author>` elements in the document.

`author/*` - All elements that are the children of `<author>` elements.

`author[1]` The first `<author>` element in the current context node.

`author[first-name][3]` - The third `<author>` element that has a `<first-name>` child.

`my:book` - The `<book>` element from the “`my`” namespace.

# XML Xpath (shredding) Terminology

- EXTRACT(XMLTYPE\_instance,XPath\_string) or  
EXTRACT(XMLTYPE\_instance,XPath\_string, namespace\_string)  
  
EXTRACT (XML) - It applies a VARCHAR2 XPath string and returns an XMLType instance containing an XML fragment. You can specify an absolute XPath\_string with an initial slash or a relative XPath\_string by omitting the initial slash. If you omit the initial slash, the context of the relative path defaults to the root node. The optional namespace\_string must resolve to a VARCHAR2 value that specifies a default mapping or namespace mapping for prefixes, which Oracle Database uses when evaluating the XPath expression(s).
- getClobVal() - Returns a CLOB containing an XML document based on the contents of the XMLType.
- XMLTYPE (CLOB) – constructor; convert properly formed CLOB to XMLTYPE, raises an exception

Oracle9i has a dedicated XML datatype called XMLTYPE. It is made up of a CLOB to store the original XML data and a number of member functions to make the data available to SQL.

# XPATH Terminology

- VALUE takes as its argument a correlation variable (table alias) associated with a row of an object table and returns object instances stored in the object table. The type of the object instances is the same type as the object table.
- Table functions are functions that produce a collection of rows (either a nested table or a varray) that can be queried like a physical database table or assigned to a PL/SQL collection variable. You can use a table function like the name of a database table, in the FROM clause of a query, or like a column name in the SELECT list of a query.

# XPATH Terminology

- XMLSEQUENCE - XMLSEQUENCE(XMLTYPE\_instance)
- XMLSEQUENCE operator is used to split multi-value results from XMLTYPE queries into multiple rows.
- The first form takes as input an XMLType instance and returns a varray of the top-level nodes in the XMLType. This form is effectively superseded by the SQL/XML standard function XMLTable, which provides for more readable SQL code. Prior to Oracle Database 10g Release 2, XMLSequence was used with SQL function TABLE to do some of what can now be done better with the XMLTable function.
- Because XMLSequence returns a collection of XMLType, you can use this function in a TABLE clause to unnest the collection values into multiple rows, which can in turn be further processed in the SQL query.

# Xpath Expression Syntax

XML Document (fully qualified)

```
<?xml version="1.0" encoding="UTF-8"?> <!-- XML Declaration-->
<root>
    <parent>
        <child>robot</child>
        <child>ball</child>
    </parent>
    <parent>
        <child>airplane</child>
        <child>iPod</child>
    </parent>
</root>
```

Expression      Refers to

parent/child[1]      The first <child> of each <parent>.

(parent/child)[1]      The first <child> from the entire set of children of <parent> elements.

parent[1]/child[2]      The second <child> of the first <parent>.

parent/\*              All elements that are the children of <parent> elements.

# Namespaces Definition

- Why Namespaces – <http://www.w3.org/TR/REC-xml-names/>
- “Such documents, containing multiple markup vocabularies, pose problems of recognition and collision. Software modules need to be able to recognize the elements and attributes which they are designed to process, even in the face of "collisions" occurring when markup intended for some other software package uses the same element name or attribute name.
- These considerations require that document constructs should have names constructed so as to avoid clashes between names from different markup vocabularies. This specification describes a mechanism, *XML namespaces*, which accomplishes this by assigning expanded names to elements and attributes.”

:( :( :(

- So, in simple terms, it's a technique to distinguish two elements with the same names from each other.
- The technique allows one to import (or define) another fully qualified XML document into an existing one without causing an element name collision.

# XML Namespace Terms

- XML Namespaces - The “xmlns” Attribute

When using prefixes in XML, a so-called namespace for the prefix must be defined.

The namespace is defined by the xmlns attribute in the start tag of an element.

The namespace declaration has the following syntax.

`xmlns:prefix="URI"`.

- A Uniform Resource Identifier (URI) is a string of characters which identifies an Internet Resource.

The most common URI is the Uniform Resource Locator (URL) which identifies an Internet domain address.

# SQL XML Query (SQLX) Terminology

- Create an SQL XML query
- Defined by ISO/IEC 9075-14:2003 <sup>1</sup>
- XMLAGG() is an aggregate function. It takes a collection of XML fragments and returns an aggregated XML document.
- XMLELEMENT() takes an element name for *identifier*, an optional collection of attributes (XMLATTRIBUTES) for the element, and arguments that make up the content of the element
- XMLFOREST() converts each of its argument parameters to XML, and then returns an XML fragment that is the concatenation of these converted arguments.

<sup>1</sup> ISO/IEC 9075-14:2003 defines ways in which Database Language SQL can be used in conjunction with XML. It defines ways of importing and storing XML data in an SQL database, manipulating it within the database and publishing both XML and conventional SQL-data in XML form

# SQLX Examples – Table Contents (1\_1)

SQL> select \* from myobject;

THINGS	QUANTITY	PARENT
BALL	2	1
KEY	3	1
TABLE	1	1
FRISBEE	4	2
BBQ	1	2
SWITCH	6	2

6 rows selected.

# SQLX - XMLELEMENT Example (1\_2)

- XMLELEMENT() takes an element name for identifier, an optional collection of attributes for the element, and arguments that make up the content of the element

```
1 SELECT XMLELEMENT("thing", XMLATTRIBUTES( obj.quantity AS  
"QTY"), obj.things )  
2 AS "Object_list"  
3* FROM myobject obj  
SQL> /
```

Object\_list

---

```
<thing QTY="2">BALL</thing>  
<thing QTY="3">KEY</thing>  
<thing QTY="1">TABLE</thing>  
<thing QTY="4">FRISBEE</thing>  
<thing QTY="1">BBQ</thing>  
<thing QTY="6">SWITCH</thing>
```

6 rows selected.

# SQLX - XMLFOREST Example (1\_3)

- XMLFOREST() converts each of its argument parameters to XML, and then returns an XML fragment that is the concatenation of these converted arguments.

```
SQL> SELECT XMLFOREST(obj.quantity, obj.things) "Object_list"
2 FROM myobject obj;
```

Object\_list

---

```
<QUANTITY>2</QUANTITY><THINGS>BALL</THINGS>
<QUANTITY>3</QUANTITY><THINGS>KEY</THINGS>
<QUANTITY>1</QUANTITY><THINGS>TABLE</THINGS>
<QUANTITY>4</QUANTITY><THINGS>FRISBEE</THINGS>
<QUANTITY>1</QUANTITY><THINGS>BBQ</THINGS>
<QUANTITY>6</QUANTITY><THINGS>SWITCH</THINGS>
6 rows selected.
```

# Prettyprint or Indenting

- Formatting Convention for Output
- XML Parent Child Relationship
- Changes from 10g, 11gR1, 11gR2
- SELECT XMLSERIALIZE ( DOCUMENT -  
-line one  
(<XML\_Document>)  
• AS CLOB indent ) [ <alias> ] from dual; --  
line three

# SQLX - XMLAGG Example

(1\_4\_3) (Pretty Print)

- XMLAGG() is an aggregate function. It takes a collection of XML fragments and returns an aggregated XML document.

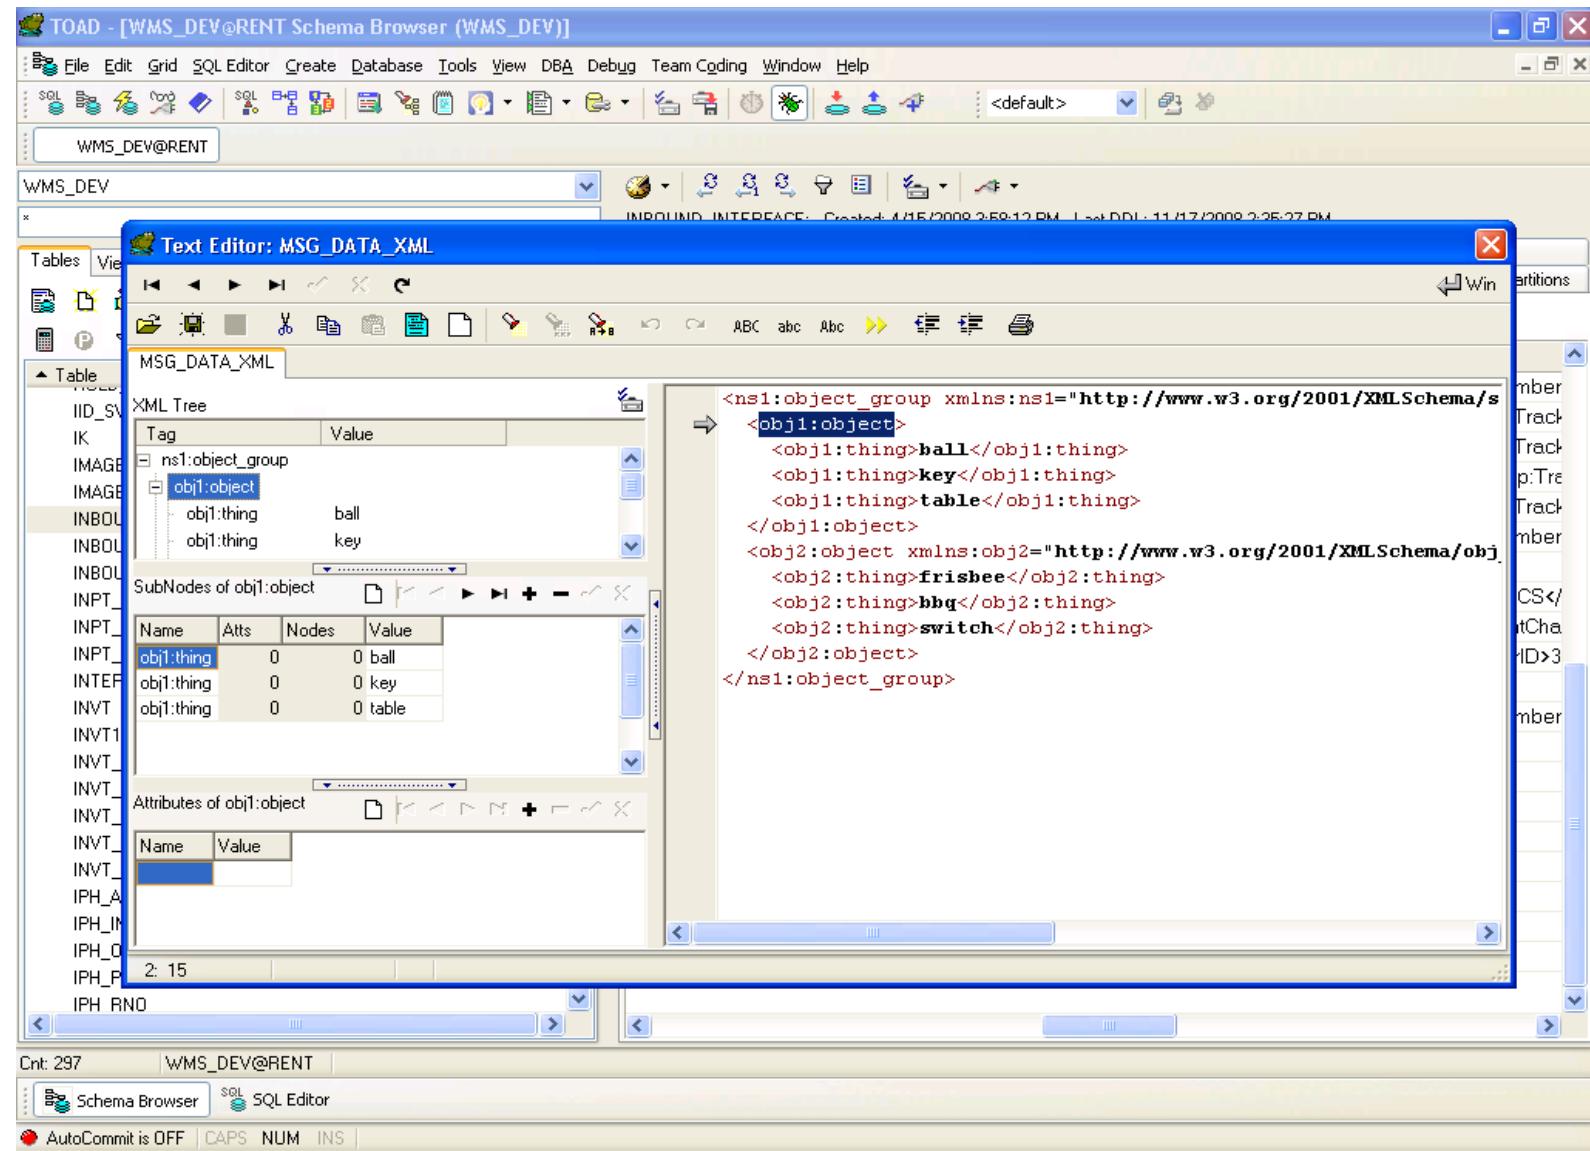

```
1 SELECT XMLELEMENT("OBJECT",
2   XMLAGG(XMLELEMENT("Things",
3     obj.things ||' '||obj.quantity ) ORDER BY obj.things)) AS "Object_list"
4 FROM myobject obj
5
6 SQL> /
```

Object\_list

---

```
<OBJECT><Things>BALL 2</Things><Things>BBQ 1</Things>
<Things>FRISBEE 4</Things><Things>KEY
3</Things><Things>SWITCH 6</Things><Things>TABLE
1</Things></OBJECT>
```

# XML Document – TOAD OUT

# XML – SQL Developer OUT

The screenshot shows the Oracle SQL Developer interface. The title bar reads "Oracle SQL Developer : TABLE WMS\_DEV.INBOUND\_INTERFACE@wms\_Dev". The menu bar includes File, Edit, View, Navigate, Run, Source, Versioning, Migration, Tools, and Help. The toolbar has various icons for connection management, file operations, and search.

The main workspace displays a table named "INBOUND\_INTERFACE". The columns are: TRAN\_CODE, MSG\_DATA, MSG\_DATA\_XML, MSG\_DATA\_CLOB, HOST\_DATA\_TYPE, DEL\_MSG\_DATA\_CLOB, and DEL\_MSG\_DATA\_CLOB. The data consists of several rows labeled TEST, each containing XML data. The XML data is also shown in the "XML Data" window, which has a tabular view with columns for TRAN\_CODE, MSG\_DATA, MSG\_DATA\_XML, MSG\_DATA\_CLOB, HOST\_DATA\_TYPE, DEL\_MSG\_DATA\_CLOB, and DEL\_MSG\_DATA\_CLOB. The XML Data window also contains an "Actions..." dropdown and a "Sort..." button.

The bottom status bar shows "Fetched Rows: 55" and "Editing".

TRAN_CODE	MSG_DATA	MSG_DATA_XML	MSG_DATA_CLOB	HOST_DATA_TYPE	DEL_MSG_DATA_CLOB	DEL_MSG_DATA_CLOB
TEST	<?xml version="1.0" encoding="UTF-8"?>	<ns1:object_group xmlns:ns1="http://www.w3.org/2001/XMLSchema/sample_namespace_1" xmlns:obj1="http://www.w3.org/2001/XMLSchema/obj_1">				
TEST		<obj1:object>				
TEST		<obj1:thing>ball</obj1:thing>				
TEST		<obj1:thing>key</obj1:thing>				
TEST		<obj1:thing>table</obj1:thing>				
TEST		</obj1:object>				
TEST		<obj2:object xmlns:obj2="http://www.w3.org/2001/XMLSchema/obj_2">				
TEST		<obj2:thing>frisbee</obj2:thing>				
TEST		<obj2:thing>bbq</obj2:thing>				
TEST		<obj2:thing>switch</obj2:thing>				
TEST		</obj2:object>				
TEST		</ns1:object_group>				

# SQLX Example – XMLAGG, XMLATTRIBUTES, Namespace (1\_5)

DECLARE

```

each element thing ball

each element thing key

each element thing table

PL/SQL procedure successfully completed.

# Oracle Text - XML Data Queries (1\_21)

- Definitions
- “contains” operator is used when index is of type context
- returns a relevance score for every row selected
- ```
select ref_id,score (1) , xmlcol
from my_xml_table
where contains (xmlcol, 'table',1) > 0
```
- Demo

# DBMS\_XML.CONVERT (1\_22\_3)

- DBMS\_XMLGEN.CONVERT - converts XML data into the escaped or unescapes XML equivalent
- Example: the escaped form of the character “>” (without the “ characters) is “&gt;” (without the “ characters).
- Oracle’s suggested “workaround” was to:
  - 1) append a space (CHR(32) to the end of the XPath string, then
  - 2) DBMS\_XMLGEN.CONVERT the string, finally
  - 3) TRIM the string. The workaround resolved the issue.

# DBMS\_XMLDOM

(1\_23)

- Parse using XPath – define expression

A whole heap of Metadata

```
<?xml version="1.0" encoding="WINDOWS-1252"?>
<StandardHeader>
  <DateTime>12/08/2010 16:03:46</DateTime>
  <PacketNumber>1</PacketNumber>
  <AnyMorePackets>Y</AnyMorePackets>
  <TotalPackets>4</TotalPackets>
  <house>
    <room>
      <room_name name="kitchen"/>
      <room_item item="sink"/>
    </room>
    |
    |
    <room>
      <room_name name="kitchen"/>
      <room_item item="table"/>
    </room>
  <house>
</StandardHeader>
```

# DBMS\_XMLDOM

(1\_24) (cont'd)

- Change XML and reduce metadata

```
<?xml version="1.0" encoding="WINDOWS-1252"?>
<StandardHeader>
  <DateTime>12/08/2010 16:03:46</DateTime>
  <PacketNumber>1</PacketNumber>
  <AnyMorePackets>Y</AnyMorePackets>
  <TotalPackets>4</TotalPackets>
<house>
